13 **Abstract**

14 This study shows the application of a total lightning data assimilation technique to the RAMS
15 (Regional Atmospheric Modeling System) forecast. The method, which can be used at high
16 horizontal resolution, helps to initiate convection whenever flashes are observed by adding water
17 vapour to the model grid column. The water vapour is added as a function of the flash rate, local
18 temperature and graupel mixing ratio. The methodology is set up to improve the short-term (3h)
19 precipitation forecast and can be used in real-time forecasting applications. However, results are
20 also presented for the daily precipitation for comparison with other studies.

21 The methodology is applied to twenty cases that occurred in fall 2012, which were characterized by
22 widespread convection and lightning activity. For these cases a detailed dataset of hourly
23 precipitation containing thousands of rain gauges over Italy, which is the target area of this study, is
24 available through the HyMeX (HYdrological cycle in the Mediterranean Experiment) initiative.
25 This dataset gives the unique opportunity to verify the precipitation forecast at the short range (3h)
26 and over a wide area (Italy).

27 Results for the 27 October case study show how the methodology works and its positive impact on
28 the 3h precipitation forecast. In particular, the model represents better convection over the sea using
29 the lightning data assimilation and, when convection is advected over the land, the precipitation
30 forecast improves over the land. It is also shown that the precise location of convection by lightning
31 data assimilation, improves the precipitation forecast at fine scales (meso- β).

32 The application of the methodology to twenty cases gives a statistically robust evaluation of the
33 impact of the total lightning data assimilation on the model performance. Results show an
34 improvement of all statistical scores, with the exception of the Bias. The Probability of Detection
35 (POD) increases by 3-5% for the 3h forecast and by more than 5% for daily precipitation,
36 depending on the precipitation threshold considered.

37 Score differences between simulations with or without data assimilation are significant at 95% level
38 for most scores and thresholds considered, showing the positive and statistically robust impact of
39 the lightning data assimilation on the precipitation forecast.

40

41 **Key words:** total lightning data assimilation, forecast verification, convective storms, cloud
42 resolving model.

43

44 **1. Introduction**

45 The inclusion of the effects of deep convection in the initial conditions of Numerical Weather
46 Prediction (NWP) models is one of the most important problem to reduce the spin-up time and to
47 improve initial conditions (Stensrud and Fritsch, 1994; Alexander et al., 1999). In recent years,
48 several studies have shown the positive impact that lightning assimilation has on the weather
49 forecast, and especially on the precipitation forecast (Alexander et al. 1999; Chang et al., 2001;
50 Papadopoulos et al., 2005; Mansell et al., 2007; Fierro et al., 2012; Giannaros et al., 2016).

51 Lightning data are a proxy for identifying the occurrence of deep convection, which relates to
52 convective precipitation (Goodman et al., 1988). In addition to their ability to locate precisely the
53 deep convection and heavy precipitation, lightning data have several advantages: availability in real
54 time with few gaps (reliability), compactness (a low band is required to transfer the data), long-
55 range detection of storms over the oceans and beyond the radars (Mansell et al., 2007).

56 Because of these properties, several techniques have been developed, in recent years, to assimilate
57 lightning data in NWP. In the first studies (Alexander et al. 1999; Chang et al., 2001), lightning
58 were used in conjunction with rainfall estimates from microwave data of polar orbiting satellites to
59 derive a relation between the cloud to ground flashes and rainfall. Then the rainfall estimated from
60 lightning was converted to latent heat nudging, that was assimilated in NWP (Jones and Macperson,
61 1997). These experiments showed a positive impact of the lightning data assimilation on the 12-24
62 h weather forecast.

63 Papadopoulos et al. (2005) nudged relative humidity profiles associated with deep convection and
64 the adjustment was proportional to the flash rate observed by the ZEUS network (Lagouvardos et

65 al., 2009). A modification of the Kain-Fritsch (Kain and Fritsch, 1993) convective parameterization
66 in COAMPS (Coupled Ocean-Atmosphere Mesoscale Prediction System; Hodur, 1997) was
67 introduced by Mansell et al. (2007). They enabled lightning to control the cumulus parameterization
68 scheme activation. Recently, Giannaros et al. (2016) implemented a similar approach in the WRF
69 model, showing the positive and statistically robust impact of the lightning data assimilation on the
70 24h rainfall forecast for eight convective events over Greece. Fierro et al. (2012) and Qie et al.
71 (2014) introduced two lightning data assimilation schemes for the WRF model intervening on the
72 mixing ratios of the hydrometeors (water vapour in the case of Fierro et al. (2012), and ice crystals,
73 graupel and snow in Qie et al. (2014)). Both studies, which are performed at cloud resolving scales,
74 show that lightning assimilation improves the precipitation forecast.

75 Most of the studies cited above are based on a case study approach. However, Giannaros et al.
76 (2016) applied the methodology to eight convective cases that occurred in Greece from 2010 to
77 2013. Considering a larger number of cases allowed them to statistically test the improvement of
78 the precipitation forecast through lightning data assimilation. Moreover, their methodology is
79 designed to be realistic and usable in the operational forecast.

80 In a recent study, Federico et al. (2014) introduced a scheme to simulate lightning in RAMS
81 (Regional Atmospheric Modeling System). Because the lightning distribution is well correlated to
82 areas of deep convection, they concluded that lightning simulation can be a useful tool to evaluate
83 the reliability of the NWP forecast in real time. In their study, however, lightning observations were
84 used as a diagnostic tool.

85 In this paper, a total lightning data assimilation algorithm is used in the RAMS model. The
86 assimilation scheme is similar to that of Fierro et al. (2012), with few modifications to account for
87 different spatial and temporal resolutions of the two studies and for the different model suites. In
88 addition, the methodology presented in this paper is designed to be used in real time NWP. This
89 paper considers the short-term forecast (3h), even if the results for daily precipitation, accumulated
90 from the 3h precipitation forecast, are also shown for completeness and for comparison with other
91 studies.

92 To evaluate statistically the impact of the lightning data assimilation on the precipitation forecast,
93 we consider twenty convective cases that occurred in fall 2012 over Italy, which is the target area of
94 this study. Most of these events occurred during the HyMeX SOP1 (Hydrological cycle in the
95 Mediterranean Experiment – First Special Observing Period), which was held from 5 September
96 2012 to 6 November 2012.

97 HyMeX (Drobinski et al., 2014; Ducroq et al., 2014) is an international experimental program that
98 aims to advance scientific knowledge of water cycle variability in the Mediterranean basin. This
99 goal is pursued through monitoring, analysis and modeling of the regional hydrological cycle in a
100 seamless approach. In HyMeX special emphasis is given to the topics of the occurrence of heavy
101 precipitation and floods, and their societal impacts, which were the subjects of the SOP1. One of the
102 products of the HyMeX-SOP1 is a database of hourly precipitation available for 2944 raingauges
103 over Italy belonging to the Italian DPC (Department of Civil Protection; Davolio et al., 2015). This
104 database extends behind the period of the HyMeX-SOP1 and contains all the events considered in
105 this paper.

106 The paper is organized as follows: Section 2 shows the RAMS configuration, the methodology used
107 to assimilate total lightning data, and the strategy used in the simulations. Section 3 gives the
108 results: first a case study of deep convection occurred over Italy during HyMeX-SOP1 is considered
109 to show how the lightning data assimilation works (Section 3.1); then the scores for the twenty
110 cases are shown in Section 3.2, which also shows the statistical robustness of the difference
111 between the precipitation forecasts of the simulations with or without total lightning data
112 assimilation. The discussion and conclusions are given in Section 4.

113

114 **2. Methodology**

115 *2.1 The RAMS model configuration*

116 The RAMS model is used in this study. This section is a brief description of the model setup, while
117 details on the model are given in Cotton et al. (2003).

118 We use two one-way nested domains at 10 km (R10) and 4 km (R4) horizontal resolutions,
119 respectively (Figure 1). The model is configured with thirty-six terrain following vertical levels for
120 both domains. The model top is at 22400 m (about 40 hPa). The distance of the levels is gradually
121 increased from 50 m to 1200 m. Below 1000 m the spacing between levels is less than 200 m,
122 above 5000 m the distance between levels is 1200 m.

123 The Land Ecosystem-Atmosphere Feedback model (LEAF) is used to calculate the exchange
124 between soil, vegetation, and atmosphere (Walko et al., 2000). LEAF uses a patch representation of
125 surface features (vegetation, soil, lakes and oceans, and snow cover) and includes several terms
126 describing their interactions as well as their exchanges with the atmosphere.

127 Explicitly resolved precipitation is computed by the WRF (Weather Research and Forecasting
128 System) – single-moment six-class microphysics scheme (WSM6; Hong et al., 2006). This scheme

129 was recently implemented in RAMS (Federico, 2016) and showed the best performance among the
130 microphysics schemes available in the model for a forecast period spanning 50 days of the HyMeX-
131 SOP1 at 4 km horizontal resolution. The WSM6 scheme accounts for the following water variables:
132 vapour, cloud water, cloud ice, rain, snow and graupel. The best configuration of Federico (2016) is
133 used in this paper and is hereafter referred to as control (CNTRL).

134 Sub-grid-scale effect of clouds is parameterized following Molinari and Corsetti (1985). They
135 proposed a form of the Kuo scheme (Kuo, 1974) accounting for updrafts and downdrafts. The
136 convective scheme is applied to the 10 km grid only.

137 The unresolved transport is parametrized by the K-theory following Smagorinsky (1963), which
138 relates the mixing coefficients to the fluid strain rate and includes corrections for the influence of
139 the Brunt-Vaisala frequency and the Richardson number (Pielke, 2002).

140 The Chen and Cotton (Chen and Cotton, 1983) scheme is used to compute short and long-wave
141 radiation. The scheme accounts for condensate in the atmosphere, but not for the specific
142 hydrometeor type.

143 The initial and dynamic boundary conditions are introduced in section 2.3.

144 Before concluding this section, it is important to note that 4 km horizontal resolution of the finer
145 grid corresponds to the grey area for convection and it is slightly below actual standards (2-3 km).
146 This resolution was motivated by operational purposes: the methodology of this paper is
147 implemented in a real-time weather forecasting system at ISAC-CNR and we study the performance
148 of this specific system. Preliminary results of the impact of the horizontal resolution on the
149 lightning assimilation are discussed in Section 4.

150 *2.2 Lightning data and assimilation procedure*

151 Lightning data used in this paper are those observed by LINET (LighTning detection NETwork;
152 Betz et al., 2009), which is a European lightning location network for high-precision detection of
153 total lightning, cloud to ground (CG) and intra cloud (IC) lightning, with utilization of VLF/LF
154 techniques (in range between 1 and 200 KHz).

155 The network has more than 550 sensors in several countries worldwide, with very good coverage
156 over central Europe and central and western Mediterranean (from 10° W to 35° E in longitude and
157 from 30° N to 65° N in latitude). The lightning three-dimensional location is detected using the time
158 of arrival (TOA) difference triangulation technique (Betz et al., 2009). The lightning strokes are
159 detected with high precision (150 m for an average distance between sensors of 200 km) in both
160 horizontal and vertical directions. The LINET “strokes” are grouped into “flashes” before

161 assimilation in the model. In particular, all events recorded by LINET that occur within 1 s and in
162 an area with a radius of 10 km are binned into a single flash (Federico et al., 2014).

163 Observed flashes are mapped onto the RAMS grid for assimilation in space and time. In particular,
164 the assimilation procedure computes the number of flashes occurring in each RAMS grid cell in the
165 past five minutes (X). Then the water vapour mixing ratio is computed as:

$$166 \quad q_v = Aq_s + B * q_s * \tanh(CX) * (1 - \tanh(DQ_g^\alpha)) \quad (1)$$

167 Where $A=0.86$, $B=0.15$, $C=0.30$, $D=0.25$, $\alpha=2.2$, q_s is the saturation mixing ratio at the model
168 atmospheric temperature, and Q_g is the graupel mixing ratio (g kg^{-1}). The water vapour mixing ratio
169 derived from Eqn. (1) is similar to Fierro et al. (2012). There are two changes: first the C coefficient
170 is larger in this study (in Fierro et al. (2012), $C=0.01$), which partially accounts for the different
171 horizontal resolutions of the remapped observed flashes (9 km in Fierro et al., (2012); 4 km in our
172 case, corresponding to the RAMS inner grid horizontal resolution) and for the different grouping
173 time interval (10 minutes in Fierro et al. (2012), and 5 minutes here). Second, the coefficient A (B)
174 is larger (smaller) in this study compared to Fierro et al. (2012; $A=0.81$ and $B=0.20$) because we
175 find a better performance with this setup. The set-up of Eqn. (1) was found by trials and errors
176 analysis for two case studies (15 and 27 October 2012) and considering two opposite needs: to
177 increase the precipitation hits and to reduce (or not increase considerably) the false alarms. It is
178 noted that Fierro et al. (2012) found little sensitivity of the results by varying A by 5%.

179 The water vapour derived from Eqn. (1) is substituted to the simulated value at a grid point where
180 electric activity is observed and RH is below 86%. By this choice we only add water vapour to the
181 simulated field, leaving it unchanged if the simulated water vapour is larger than that of Eqn. (1).
182 Moreover, the water vapour is substituted only in the charging zone (from 0 to -25°C), which is the
183 mixed-phase graupel-rich zone associated with electrification and lightning activity (MacGorman
184 and Rust, 1998). The increase of q_v , Eqn. (1), is inversely proportional to the simulated graupel
185 mixing ratio. When Q_g is 3 g/kg the second term of the right hand side of Eqn. (1) is ineffective (see
186 Figure 7 of Fierro et al. (2012) for the dependency of Eqn. (1) on the graupel mixing ratio). For a
187 given value of Q_g between 0 and 3 g/kg, the water vapour of Eqn. (1) increases as a function of the
188 gridded flash rate X .

189 It is noted that we change the water vapour in the charging zone between 0°C and -25°C , without a
190 relaxing zone. The water vapour, however, is redistributed by the model advection, diffusion and
191 diabatic processes, and is considerably changed outside the charging zone (see the discussion of this
192 paper; Federico et al. 2016).

193

194 *2.3 Simulation strategy and verification*

195 Twenty case studies that occurred in fall 2012 were selected. The events are reported in Table 1 and
196 were all characterized by widespread convection, lightning activity, and moderate-heavy
197 precipitation over Italy. The events of Table 1 comprise eight of the nine IOP (Intense Observing
198 Period) declared in Italy (see Table 5 of Ferretti et al. (2014) for the complete list of the IOP) during
199 HyMeX-SOP1 and few other cases of November 2012.

200 A 36 h forecast at 10 km horizontal resolution is performed for each case (R10). The initial and
201 boundary conditions (BC) for this run are given by the 12 UTC assimilation/forecast cycle of the
202 ECMWF (European Centre for Medium Weather range Forecast). Initial and BC are available at
203 0.25° horizontal resolution. The R10 forecast starts at 12 UTC of the day before the day of interest
204 (actual day, Table 1) and the first 12 hours, which also account for the spin-up time, are discarded
205 from the evaluation. The R10 forecast is made to give the initial and BC to the 4 km horizontal
206 resolution forecast (R4), avoiding the abrupt change of resolution from the ECMWF initial
207 conditions and BC (0.25°) to the R4 horizontal resolution.

208 Starting from R10 as initial and BC, three kind of simulations, all using the R4 configuration, are
209 performed for each event: a) CNTRL: this simulation is performed by nesting R4 in R10 using a
210 one-way nest and without doing lightning data assimilation. Each CNTRL simulation starts at 18
211 UTC of the day before the actual day and the first six hours, which account for the spin-up time, are
212 discarded from the evaluation; b) F3HA6: these simulations consist of eight runs of 9 h duration.
213 During the first 6 h, lightning data are assimilated following the procedure described in the previous
214 section. Then, a short term 3 h forecast is made. Eight F3HA6 simulations are needed to span the
215 forecast of a whole day (Figure 2). The first simulation starts at 18 UTC of the day before the actual
216 day, using as initial and boundary conditions the R10 forecast, and gives the forecast for the hours
217 00-03 UTC of the actual day. The second F3HA6 simulation starts at 21 UTC of the day before the
218 actual day using as initial conditions the previous R4 forecast, belonging to F3HA6 set of
219 simulations, and as BC the R10 forecast. Lightning are assimilated from 21 UTC of the day before
220 to 03 UTC of the actual day, while the forecast is valid for 03-06 UTC of the actual day. The
221 F3HA6 forecasts from three to eight proceed as the second but shifted every time three hours ahead.
222 Please note the switch of the initial conditions between the first and second F3HA6 simulations
223 from R10 to R4. This is done to maximise the impact of lightning data assimilation on the F3HA6
224 run, since the initial conditions provided by R4 are produced by a simulation using lightning data,
225 while in R10 lightning data are not used; c) ASSIM: this simulation is performed by nesting R4 in

226 R10 using a one-way nest and doing lightning data assimilation for the whole run. Each ASSIM
227 simulation starts at 18 UTC of the day before the actual day and the first six hours of forecast are
228 considered as spin-up time and are discarded from the evaluation. The ASSIM simulation
229 continuously assimilates lightning data and, because it represents better convection during the
230 events compared to CNTRL and F3HA6, has the best performance (Section 3.2). The ASSIM
231 configuration can be useful when analysing the events but cannot be used for the forecast because it
232 needs real-time lightning data as the integration time advances.

233 It is noted that the configuration F3HA6 was chosen because it can be applied in the operational
234 context. The simulation R10 takes less than one hour to complete the 36 h forecast on a 64 core
235 state of the art cluster. Each simulation F3HA6 takes 20-25 minutes using a 64 cores state of the art
236 cluster, which makes the forecast available for operational purposes. Continuous advancing of
237 computing power will give the possibility to apply the methodology at finer horizontal resolutions
238 for extended areas, as that considered in this paper, as well as to reach the kilometeric scale for
239 limited areas.

240 Even if the main focus of this paper is on the short-term (3 h) forecast, the daily precipitation
241 accumulated from the 3h forecasts is also considered for comparison with other studies available in
242 the literature. For F3HA6 the daily precipitation is given by adding the eight 3 h forecasts available
243 for the actual day (Figure 2).

244 One of the products of the HyMeX initiative is a database of hourly precipitation from the network
245 of the DPC of Italy, which consists of 2944 rain gauges all over Italy. The dataset is available at
246 http://mistrals.sedoo.fr/?editDatsId=1282&datsId=1282&project_name=MISTR&q=DPC and it is
247 used to derive 3 h and daily rainfall, which are then used to verify the model.

248 For the verification of the Quantitative Precipitation Forecast (QPF), the model output at the closest
249 grid point of a raingauge is considered. When two or more raingauge fall in the same model grid-
250 cell, the average precipitation recorded by these raingauges is considered.

251 Statistical verification is performed by 2x2 contingency tables for different precipitation thresholds.
252 For the 3 h rainfall comparison the thresholds are: 0.2, 1.0, 3.0, 5.0, 7.5, 10.0, 15.0, 20 mm/3h. For
253 daily precipitation the thresholds are: 1, 5, 10, 20, 40, 60 mm/day, with 60 mm/day (7.5 mm/3h)
254 considered as the threshold for severe precipitation events in the Mediterranean Basin (Jansà et al.,
255 2014). From the hits (*a*), false alarms (*b*), misses (*c*), and correct no forecasts (*d*) of the contingency
256 tables, the probability of detection (POD; range [0, 1], where 1 is the perfect score, i.e. when no
257 misses and false alarms occur), the False Alarm Ratio (FAR; range [0, 1], where 0 is the perfect

258 score), the Bias (range $[0, +\infty)$, where 1 is the perfect score) and the equitable threat score (ETS;
259 range $[-1/3, 1]$, where 1 is the perfect score and 0 is a useless forecast) are computed (Wilks, 2006):

$$\begin{aligned} POD &= \frac{a}{a+c} \\ FAR &= \frac{b}{a+b} \\ Bias &= \frac{a+b}{a+c} \\ ETS &= \frac{a-a_r}{a+b+c-a_r}; \text{ and } a_r = \frac{(a+b)(a+c)}{a+b+c+d} \end{aligned} \quad (1)$$

261 where a_r is the probability to have a correct forecast by chance (Wilks, 2006).

262 The POD gives the fraction of the observed rain events that were correctly forecast. The FAR gives
263 the fraction of rain forecast events that didn't occur. The Bias tells us the fraction of rain forecast
264 events with respect to the rain observed events. The ETS measures the fraction of observed and/or
265 forecast rain events that were correctly predicted, adjusted for hits associated to a random forecast,
266 where the forecast occurrence/non-occurrence is independent of observation/non observation.

267 In order to have a measure of the difference between the CNTRL and F3HA6 forecast, a hypothesis
268 test to verify that the score difference between the two competing models is significant at a
269 predefined significance level (90%, $\alpha=0.1$; or 95%, $\alpha=0.05$) is made. The test was originally
270 proposed by Hamill (1999), is based on resampling, and is discussed in Appendix A.

271

272 **3. Results**

273

274 *3.1 The 27 October 2012 case study*

275 The event studied in this section is taken from the HyMeX SOP1 campaign, which was focused on
276 heavy precipitation and its societal impact (Ducroq et al., 2014; Ferretti et al., 2014). Nine of the
277 twenty IOPs (Intense Observing Period) considered in SOP1 occurred in Italy.

278 During SOP1, several upper level troughs extended from the Northern and Central Europe toward
279 the Mediterranean Basin or entered in the Basin as deep trough. Few of them developed a cut-off
280 low at 500 hPa; the interaction between the upper level troughs and the orography of the Alps
281 generated a low pressure pattern at the surface in Northern Italy, and usually the whole system
282 moved along the Italian peninsula. The 27 October 2012 case study, also referred as IOP16a,

283 belongs to this class of events, and it eventually evolved in a cut-off at 500 hPa on 28-29 October
284 (IOP16c). This event, characterized by widespread convection and intense lightning activity, caused
285 huge precipitation all along the peninsula and also peak values of water level on the Venice Lagoon,
286 where the sea level exceeded twice the warning level of 120 cm (Casaioli et al., 2013; Mariani et
287 al., 2014).

288 Figure 3 shows the synoptic situation at 12 UTC on 27 October 2012. At 500 hPa, Figure 3a, a
289 trough extends from NE Europe toward the Western Mediterranean. The interaction between the
290 trough and the Alps generated a mesolow over northern Italy, as shown by the 990 hPa contour in
291 Figure 3b, that caused a cyclonic circulation over most of the peninsula.

292 In these synoptic conditions, winds over the Tyrrhenian Sea are from W and SW and bring humid
293 and unstable air over the mainland of Italy. The interaction between the unstable air and the
294 orography of Italy reinforced convection, which, however, was already occurring over the sea as
295 shown by the intense electric activity over the Tyrrhenian Sea (see below).

296 Figure 4a shows the lightning distribution observed by LINET on 27 October 2012. From Figure
297 4a, convection is apparent over the Tyrrhenian Sea and it is enhanced over land because of the
298 interaction between the humid and unstable air masses from the sea and the orography of Italy.

299 The daily precipitation (Figure 4b), which is unavailable for a wide area of Central-Northern Italy,
300 shows the widespread convection over the Apennines, with several stations reporting more than 90
301 mm/day. More than 200 mm are reported in two stations in Southern Italy (15.84E, 40.31N; 207
302 mm) and (15.98E, 40.16N; 220 mm), while the largest precipitation recorded in NE Italy is 141 mm
303 (13.54E, 45.85N). Note also the abundant precipitation over Sardinia and over the North-East of
304 Italy. It is important to note that the rainfall of Figure 4b is computed by summing the 1h
305 precipitation registered by the rain gauges. If one of the 1h observations is unavailable, the
306 rain gauge does not appear in Figure 4b. So, when verifying the precipitation for shorter time scales,
307 different rain gauges could appear compared to those of Figure 4b.

308 Figures 5a and 5b show the daily precipitation forecast of the CNTRL run and the daily
309 accumulated precipitation of the F3HA6 run. Figures 5a and 5b shows a high precipitation amount
310 over the Apennines (> 90 mm/day) all along the peninsula, in agreement with observations.
311 However, the precipitation is overestimated by both CNTRL and F3HA6, especially above 30
312 mm/day. This is apparent by comparing the area of the 90 mm/day threshold in Figures 5a-5b with
313 the comparatively few rain gauges reporting this precipitation amount. As it will be shown in the
314 next section, this is a general behaviour of the RAMS model with the setup used in this paper. Other
315 features shown by Figures 5a and 5b are: a very heavy precipitation spell in NE Italy, whose area is

316 overestimated by CNTRL and F3HA6; a high precipitation spell over the Liguria-Tuscany area,
317 which is only partially revealed by observations due to the lack of data; a moderate precipitation
318 over Sardinia, which is underestimated by the CNTRL forecast both for the precipitation area and
319 amount.

320 Even if CNTRL and F3HA6 share several precipitation features in common, there are important
321 differences between Figures 5a and 5b. Convection over the sea is underestimated by CNTRL.
322 Even if we cannot prove it by the precipitation amount, the intense electrical activity over the
323 Central Mediterranean Sea, and especially over the Tyrrhenian Sea, shows that the convective
324 activity over the sea is underestimated by CNTRL.

325 Convection over the sea is simulated by F3HA6 thanks to the lightning data assimilation. When
326 convection is advected over the land it increases the precipitation. This is clearly shown by the
327 precipitation over Sardinia, which increases both in areal coverage and rainfall amount for F3HA6
328 compared to CNTRL.

329 Other differences between the precipitation field of CNTRL and F3HA6 can be discussed more
330 easily by the difference of the precipitation fields. Figure 5c shows the precipitation difference
331 between CNTRL and F3HA6 in this order, so that positive values show larger precipitation for
332 CNTRL, while negative values show larger precipitation for F3HA6.

333 From Figure 5c it is apparent that the precipitation of F3HA6 increases over large areas of the
334 domain, especially over the Tyrrhenian Sea. The rainfall over Sardinia increases up to 40 mm/day,
335 showing the important impact of the lightning assimilation on the forecast. However, the largest
336 differences are found along the Apennines with values up to 80 mm/day.

337 In general, the lightning assimilation increases the precipitation, nonetheless Figure 5c shows also
338 areas where the precipitation of F3HA6 decreases compared to CNTRL, because of the different
339 evolution of the storm in the two simulations. This is especially evident over the Adriatic coast of
340 the Balkans where positive-negative patterns alternate every few tens of kilometres. We will discuss
341 further this point later on in this section.

342 Up to now, we considered the impact of the lightning assimilation on the daily precipitation, i.e.
343 when the rainfall of the eight F3HA6 forecasts in a day are added, however the main focus of this
344 paper is on the short-term precipitation forecast. To consider this point, Figure 6a shows the
345 observed precipitation accumulated between 06 and 09 UTC, and the corresponding precipitation
346 for the CNTRL (Figure 6b) and F3HA6 (Figure 6c).

347 Figure 6a shows considerable precipitation spells (about 40 mm/3h) over NE Italy, in some spots
348 over the Apennines all along Italy, and, somewhat smaller, over Sardinia.

349 Comparing Figure 6b with Figure 6a it is apparent that the CNTRL forecast is able to catch several
350 features of the precipitation field, as the local spots of heavy rain over the Apennines or the rain
351 spell over NE Italy, the main error being the scarce precipitation simulated over Sardinia. This issue
352 is in part solved by the F3HA6 forecast (Figure 6c), which shows larger precipitation compared to
353 CNRTL over Sardinia.

354 To better focus on the improvement given by the lightning data assimilation on the short term QPF,
355 we consider the precipitation hits, i.e. the correct forecasts, of the contingency tables. Figure 7a
356 shows the difference between the hits of the F3HA6 and CNTRL (in this order) for the 1 mm/3h (8
357 mm/day) threshold. In Figure 7a, the +1 (red asterisk) shows a station where the CNTRL forecast
358 did not predict a precipitation equal or larger than the threshold, while the F3HA6 correctly
359 predicted a rainfall equal or larger than the threshold at the raingauge. The -1 value (blue asterisk)
360 shows the opposite behaviour. In Figure 7a there are fifty-two new correctly predicted events for
361 F3HA6. They are located in the Apennines and, mostly, over Sardinia, where CNTRL missed the
362 forecast (Figures 5a-5b). There are also two stations where the lightning assimilation worsens the
363 forecast, because of the different evolutions of the storms in CNTRL and F3HA6, nevertheless the
364 benefits of the lightning data assimilation on the short term QPF are apparent for the 1 mm/3h
365 threshold.

366 Figure 7b shows the difference between the hits of F3HA6 and CNTRL for the 10 mm/3h (80
367 mm/day) threshold, which is more interesting when considering moderate-high rainfall amounts.
368 For this threshold, the lightning data assimilation improves the forecast because twelve new events
369 are correctly predicted by F3HA6 along the Apennines and over Sardinia.

370 It is important to note the precision of the correction to the precipitation field given by the lightning
371 data assimilation. The positive-negative pattern of the difference between the precipitation fields of
372 CNTRL and F3HA6 (shown for the daily precipitation, Figure 5c, with amplitudes of tens of
373 kilometres in the Central Apennines) is found, with lower amplitude, also for the 3h forecast (not
374 shown). The F3HA6 forecast gave the correct prediction of several new stations for both 1 mm/3h
375 (fifty-two raingauges) and 10 mm/3h (twelve raingauges) thresholds, while losing only two stations
376 correctly predicted by CNTRL for the 1 mm/3h threshold. This shows that the precipitation is added
377 where necessary, but also that it is subtracted where it did not occur, i.e. only two correct forecasts
378 are lost by the lightning data assimilation. For example, between 03 and 06 UTC there are 110

379 stations where the precipitation is reduced by more than 1 mm/3h, 20 stations where it is reduced by
380 more than 5 mm/3h, and 7 stations for which the precipitation is reduced by more than 10 mm/3h.

381 It is worth noting that the stations correctly forecast by both CNTRL and F3HA6 for a given
382 precipitation threshold do not appear in Figures 7a and 7b. This occurs, for example, for the
383 raingauges in NE Italy.

384 This section showed how the data assimilation technique of this study works and how it is able to
385 add new correct forecasts (hits) to CNTRL for a case study. In the following section, scores based
386 on contingency tables are presented for a total of twenty case studies in order to quantify, in a
387 statistically robust way, the benefits of the total lightning data assimilation on the short-term QPF.

388

389 *3.2 Statistical scores*

390 In this section we discuss the statistical scores of the F3HA6 forecast in comparison to CNTRL.
391 The results of the ASSIM run are also presented as the benchmark for lightning data assimilation.
392 First we discuss the results for the daily precipitation accumulated starting from 3h rainfall
393 forecasts.

394 Figure 8a shows that the Bias increases with the threshold from 0.8-1.0 (1 mm/day threshold,
395 depending on the type of simulation) to 2.3-2.6 (60 mm/day threshold), showing a considerable
396 overestimation of the forecast area for the larger thresholds (> 40 mm/day). The lightning data
397 assimilation improves the Bias up to 10 mm/day (both F3HA6 and ASSIM), while performance is
398 worsened by data assimilation for larger thresholds. As expected, the ASSIM shows the largest
399 Bias, followed by F3HA6 and CNTRL. This is caused by the addition of water vapour by the data
400 assimilation, which is larger for ASSIM (assimilation performed continuously) compared to F3HA6
401 (assimilation is not performed in the forecast phase). The statistical test to assess the bias difference
402 between CNTRL and F3HA6 shows that the two scores are different at 95% significance level for
403 all thresholds, showing the significant impact of the lightning data assimilation on the precipitation
404 forecast.

405 The overestimation of the precipitation area for higher thresholds is well evident, as discussed in the
406 previous section, in Figures 5a-5b over the Apennines for the 90 mm/day threshold (the ASSIM
407 simulation, not shown, does not differ substantially from F3HA6). Comparing the result of the Bias
408 with the same result of Federico (2016), where the same configuration of the RAMS model of
409 CNTRL was used, we note a considerable increase of the Bias in this work. This difference is
410 caused by the fact that Federico (2016) considered 50 consecutive days of the HyMeX-SOP1, i.e.
411 with heavy, moderate and small precipitation, while this study considers only cases with deep and

412 widespread convection. The RAMS with WSM6 scheme shows the tendency to overestimate the
413 Bias for increasing precipitation (Federico, 2016; see also Liu et al., 2011 for a general comparison
414 of the WSM6 microphysical scheme and other microphysical schemes available in the Weather
415 Research and Forecast (WRF) model), and this tendency is amplified for the heavy precipitation
416 events considered in this work.

417 Figure 8b shows the ETS score. For CNTRL it decreases from 0.35 (1 mm/day) to 0.17 (60
418 mm/day). The ETS increases for F3HA6, especially for thresholds lower than 40 mm/day, showing
419 the positive impact of the lightning assimilation on the precipitation forecast. The difference of the
420 ETS for F3HA6 and CNTRL is statistically significant at 95% level for thresholds up to 20
421 mm/day, and not significant for larger precipitation. The ASSIM simulations show a further
422 increase of the ETS compared to F3HA6 because of their ability to better represent convection
423 during the simulation through lightning data assimilation.

424 The POD (Figure 8c) for CNTRL decreases from 0.70 (1 mm/day) to 0.52 (60 mm/day), i.e. half of
425 the potentially dangerous events are correctly predicted. It is also noted the rather stable value of the
426 POD (0.6) between the 10 and 40 mm/day thresholds. The POD increases for F3HA6. The lowest
427 increment is attained for 60 mm/day (0.04, i.e. 4% more potentially dangerous events are correctly
428 forecast compared to CNTRL), the largest for the 1 mm/day (6.5%). Differences between the POD
429 of CNTRL and F3HA6 are significant at 95% level for all thresholds showing the robust
430 improvement of the performance for this score using lightning data assimilation. Notably, the
431 ASSIM run increases the POD of 8-10%, depending on the threshold.

432 The FAR for CNTRL (Figure 8d) increases from less than 0.2 (1 mm/day threshold; i.e. less than
433 20% of the forecasts are false alarms) to 0.8 (60 mm/day threshold; i.e. 80% of the forecasts are
434 false alarms). The lightning assimilation improves the performance for the FAR but differences are
435 statistically significant for 1 mm/day (90% level), 5 and 10 mm/day (95% level). The inspection of
436 the contingency tables shows that the improvement of the FAR for those thresholds is attained by a
437 larger number of hits but there is also an increase of the false alarms. In general, the lightning
438 assimilation increases the precipitation, which is already overestimated for the larger thresholds by
439 CNTRL. So, the POD and the hit rate are increased by lightning data assimilation, but also the false
440 alarms, which were already reported in CNTRL, especially for the larger thresholds (> 30 mm/day).
441 Anyway, we believe that the result is overall helpful for operational purposes.

442 Figure 9a shows the Bias for the 3h precipitation forecast. The Bias for CNTRL increases from
443 about 1 (0.2 mm/3h threshold) to 2.5 (20 mm/3h threshold). The Bias differences between CNTRL
444 and F3HA6 are significant at 95% level for all thresholds.

445 The ETS score (Figure 9b) for CNTRL shows a decrease from 0.33 (0.2 mm/3h threshold) to 0.13
446 (20 mm/3h threshold). The ETS is larger for F3HA6 compared to CNTRL and the differences of the
447 scores are significant at 95% level for all thresholds. It is also noted that, while the ETS is positive
448 for all thresholds, the ETS value is rather low for the 20 mm/3h threshold, limiting the usefulness of
449 the forecast.

450 Figure 9c shows the POD for the 3h forecast. The value for CNTRL decreases from 0.63 (0.2
451 mm/3h) to 0.43 (20 mm/3h). The POD increases for F3HA6, notably for thresholds up to 7.5
452 mm/3h (>5%), while the improvement is smaller (3%-4%) for larger thresholds.

453 Figure 9d shows the FAR for the 3h forecast. The FAR increases from 0.3 to 0.83 for the CNTRL
454 forecast. The FAR for F3HA6 decreases (1-3% depending on the threshold) and the improvement is
455 the result of the increase of the hits but it is also associated to an increase of the false alarms.

456

457 **4. Discussion and conclusions**

458 This study shows the application of a total lightning data assimilation technique, developed by
459 Fierro et al. (2012), to the RAMS model with WSM6 microphysics scheme (Federico, 2016). The
460 technique adds water vapour to grid columns where flashes are observed, and the water vapour
461 added at constant temperature depends on the flash rate and on the graupel mixing ratio. Water
462 vapour is added to the model when suitable, while the water vapour is unchanged when the model
463 predicts a value larger than that of the data assimilation algorithm. This paper shows a realistic
464 implementation of the assimilation/forecast procedure that can be adopted in operational weather
465 forecast.

466 The results of this paper show that the methodology is effective at improving the short-term (3h)
467 precipitation forecast. More in detail, the analysis of the 27 October shows that the total lightning
468 data assimilation is able to trigger convection over the sea and, when convection is advected over
469 the land, it improves the short-term precipitation forecast. This effect is apparent over Sardinia for
470 the case study. The humid marine air masses interact with the local orography causing or
471 reinforcing convection. Also, the lightning data assimilation improves the rainfall forecast adding
472 precipitation where it is observed and increasing the hits of the short-term forecast.

473 The advection of convection from the sea to the land was important in most case studies considered
474 in this paper, and we can conclude that it plays a fundamental role. There are cases, however, when
475 it is less important, as for the severe and localized storm that occurred in NE Italy on 12 September
476 2012 (Manzato et al., 2014). For this case, the storm developed and evolved over land, and the

477 difference between the precipitation field of the CNTRL and F3HA6 is confined inland, over NE
478 Italy, and it is larger than 40 mm (see the discussion of this paper for the map of the precipitation
479 difference between CNTRL and F3HA6; Federico et al., 2016).

480 The analysis of the scores for the 3h precipitation forecast, computed for twenty cases characterized
481 by intense lightning activity and widespread convection, confirms the improvement of the
482 precipitation forecast using lightning data assimilation. The ETS and POD increase for all
483 thresholds considered for F3HA6 compared to CNTRL and the difference between the scores of the
484 competing forecasts is significant at 95% level for all thresholds. The FAR is also improved and the
485 difference between the scores of F3HA6 and CNTRL is statistically significant for all thresholds
486 with the exception of the 15 mm/3h. The FAR improvement of F3HA6 is caused by the increase of
487 the hits, but it is also associated to a larger number of false alarms.

488 The Bias is the only score that worsens with lightning data assimilation. The Bias of the RAMS
489 model with the WSM6 microphysics scheme is larger than one for most thresholds for the case
490 studies of this paper. Because the lightning data assimilation adds water vapour to the model, the
491 tendency to overestimate the precipitation area, especially for the larger thresholds, is worsened by
492 the lightning data assimilation.

493 In addition to the 3h forecast, the scores and precipitation field are analysed for the daily
494 precipitation for completeness and for comparison with other studies. Recently, Giannaros et al.
495 (2016) presented the WRF-LTNGDA, a lightning data assimilation technique implemented in
496 WRF. They presented the results for eight cases in Greece. Their assimilation strategy focuses on
497 the daily rainfall prediction (tomorrow daily precipitation). Their analysis (see their Figure 3, note
498 also that the maximum precipitation threshold is 20 mm/day in their study) shows that the POD
499 increases when lightning data assimilation is compared to CNTRL, and the increase of the POD is
500 up to 5%. Moreover, for some thresholds, the lightning assimilation lowers the POD because of the
501 different patterns followed by the storms in the simulations with or without lightning data
502 assimilation.

503 Our results show that the POD improves for all precipitation thresholds when lightning data
504 assimilation is used and the percentage of improvement is slightly better than that reported in
505 Giannaros et al. (2016) for the lower thresholds (below 10 mm/day). Even if we cannot give a
506 definitive answer to this issue, because of the many important differences between this study and
507 that of Giannaros et al. (2016), the lightning data assimilation technique has a role. In our case,
508 lightning data are assimilated also for the actual day (6h assimilation before the forecast start time
509 followed by 3h forecast, Figure 2), while in Giannaros et al. (2016) the assimilation is done only for

510 the day before the actual day (6h assimilation followed by 24 h forecast). So, our technique should
511 improve the correct location of convection during the actual day compared to their approach, as
512 shown by the improvement, i.e. the difference between the POD of the simulations with or without
513 lightning data assimilation.

514 However, other differences play a role: first the two studies refer to different regions and to
515 different events. In our case the extension of the region, the number of the events, and the number
516 of verifying stations are larger. Moreover, two different model suites are used (WRF and RAMS).
517 These differences are clearly seen in the score values. The POD of Giannaros et al. (2016), is larger
518 than that of this study, especially for thresholds lower than 20 mm/day. Another important
519 difference arises from the different convective nature of the storms considered in the two works.
520 The performance of the precipitation forecast is clearly dependent on the type of event, i.e.
521 widespread or localized convection (Giannaros et al., 2016) and, because the events considered in
522 the two studies are different, the comparison can be only qualitative. Nevertheless, both studies
523 show that the lightning data assimilation improves the precipitation forecast robustly, and can be
524 used in the operational context.

525 While the results of this study are encouraging, there are a number of issues that need further
526 investigation. The water vapour is added to the grid column where the lightning is observed.
527 However, the lightning is often the result of a process involving larger scales than the horizontal
528 grid spacing considered in this paper (4 km). A spatial extension of the influence of the lightning
529 perturbation on the water vapour field should be explored. For this approach the applications of the
530 methods involving the model error matrix are foreseeable and will be investigated in future studies.
531 The problem of the spatial extension of the water vapour perturbation caused by lightning to the
532 model was considered in Fierro et al. (2012) by remapping the flashes onto a coarser horizontal
533 resolution grid (9 km), while no similar approach is done in this study.

534 A problem arising with the RAMS model using the WSM6 microphysics scheme is the
535 overestimation of the precipitation area for large rainfall thresholds. This tendency was already
536 noted in Federico (2016), and it is amplified for the cases of widespread convection considered in
537 this study. The high number of false alarms decreases the ETS score for high precipitation, reducing
538 the applicability of the method for the largest thresholds (> 100 mm/day). The application of
539 different microphysical schemes could mitigate this issue.

540 Finally, horizontal resolutions higher than that of this paper are needed to better resolve the
541 orography and its interaction with air masses. To quantify this point preliminary, we increased the
542 horizontal resolution of the second domain from 4 km to 2.5 km for the 15 October and 27 October

543 case studies. Results for the two cases show that the impact of the resolution is notable because the
 544 precipitation patterns, especially for larger thresholds (>50 mm/day), are less spread in the 2.5 km
 545 horizontal resolution experiment compared to 4 km forecast (see the discussion of this paper for the
 546 daily precipitation maps for the two cases, Federico et al., 2016). This impact could be beneficial
 547 for the scores of the F3HA6 forecast because it has the tendency to overestimate the precipitation
 548 area at high thresholds, as shown in this paper. However, these results are preliminary, and future
 549 studies are needed to quantify the important impact of the horizontal resolution on the lightning data
 550 assimilation forecast.

551

552 **Appendix A**

553 We use the resampling method introduced by Hamill (1999) for the comparison of the scores of
 554 CNTRL and F3HA6 forecasts (see also Accadia et al. (2003) and Federico et al. (2003)).

555 The null hypothesis is that the difference of the scores of the two competing models, CNTRL and
 556 F3HA6, is zero:

$$557 \quad H_0: S_1 - S_2 = 0 \quad (A1)$$

558 Where S is the generic score (Bias, ETS, POD and FAR), 1 is the CNTRL forecast and 2 is the
 559 F3HA6 forecast. The scores are computed from the sum of the contingency tables of the CNTRL
 560 and F3HA6 forecasts to minimize the sensitivity of the test to small changes of the contingency
 561 table elements.

562 In this paper the number of contingency tables available is 8 multiplied the number of days, i.e.
 563 $n=20*8=160$ for the 3h precipitation forecast, and $n=20$ for the daily precipitation forecast.

564 Indicating the contingency tables by the vector \mathbf{x} :

$$565 \quad \mathbf{x}_{i,j} = (a, b, c, d)_{i,j} \quad (A2)$$

566 where i is the competing model ($i=1$ for CNTRL, $i=2$ for F3HA6) and j is the contingency table ($j=$
 567 $1, \dots, 180$ for 3h forecast, and $j=1, \dots, 20$ for daily precipitation), the scores are computed from the
 568 sum of the contingency tables:

$$569 \quad S_i = f\left(\sum_{j=1}^n x_{i,j}\right) \quad (A3)$$

570 and the test statistic is given by the difference between S_1 and S_2 .

571 The bootstrap method is applied by resampling the contingency tables in a consistent way. For this
 572 purpose, a random number I_j is generated, which can assume the values 1 or 2. If I_j is 1 the
 573 contingency table of CNTRL is selected, if I_j eq 2 the F3HA6 table is selected. The process is

574 repeated for each contingency table ($j=1,\dots,180$ for 3h forecast, and $j=1,\dots,20$ for daily
575 precipitation) and the scores S_1^* and S_2^* are computed:

$$576 \quad S_1^* = f\left(\sum_{j=1}^n x_{I_j,j}\right); \quad S_2^* = f\left(\sum_{j=1}^n x_{3-I_j,j}\right) \quad (A4)$$

577 So, the two j -th contingency tables are swapped if $I_j=2$, while the swapping is not performed for
578 $I_j=1$.

579 This random sampling is performed a large number of times (10.000 in this paper). Each time the
580 scores are computed from the sum of the elements of the resampled contingency tables, Eqn. (A4),
581 to make the null distribution ($S_1^* - S_2^*$) of the difference between the scores of the competing
582 forecasts.

583 Then we compute the t_L and t_U that represent the $\alpha/2$ and $(1-\alpha)/2$ percentile of the null distribution
584 ($S_1^* - S_2^*$). The null hypothesis that the score difference between the two competing forecasts is zero
585 is rejected at the level 90 % ($\alpha=0.1$) or 95% ($\alpha=0.05$) if:

$$586 \quad (S_1 - S_2) < t_L \quad \text{or} \quad (S_1 - S_2) > t_U \quad (A5)$$

587 where S_1 and S_2 are the generic scores of the actual distributions (not resampled).

764 Figure 3: Synoptic situation at 12 UTC on 27 October 2012; a) 500 hPa: temperature (black
 765 contours from 236 K to 269 K every 3 K), geopotential height (filled contours, values shown by the
 766 colour bar at the bottom) and wind vectors (maximum wind value 41 m/s); b) surface: Sea level
 767 pressure (contour from 975 to 1020 hPa every 5 hPa, the thick line is the 990 hPa contour),
 768 equivalent potential temperature (filled contours, values shown by the colour bar at the bottom), and
 769 winds (maximum wind vector is 17 m/s) simulated at 25 m above the underlying surface in the
 770 terrain-following coordinates of RAMS. This figure is derived from the RAMS run at 10 km
 771 horizontal-resolution. The bottom and left axes show the grid point number, while the top and right
 772 axes show the geographical coordinates.
